REMARKS

Claims 1, 3-6 and 8-14 are pending and under consideration in this application. Claims 1, 6, 11, and 14 are amended herein. Support for the amendments to the claims may be found at page 11, lines 11-25, continuing at page 12, line 1 of the specification. Reconsideration is requested based on the foregoing amendment and the following remarks.

Response to Arguments:

The Applicants appreciate the consideration given to their arguments. The Applicants, however, were disappointed to find that their arguments were not found to be persuasive. The final Office Action asserts at page 9, lines 14, 15, and 16, that:

From at least these citations, it is clear that the input properties of the [JavaBean] object are equivalent to the claimed "retrieval condition." In other words, as Ims' input properties are used in the function of a database lookup to get results, that they sufficiently teach the claimed retrieval condition.

This is submitted to be incorrect. Neither a category name nor a book title, both of which are given as examples of input properties at column 10, lines 51 and 52 of lms, are equivalent to a retrieval *condition*, whether or not they are used in retrieving available book inventory information. The input properties of lms, rather, are used in the function of a database lookup to get *results*, as noted in the final Office Action.

The final Office Action goes on to assert at page 10, lines 12-15, that:

In other words, the Examiner submits that Ims executes the input properties of the cached object to obtain a fresh copy of results, and therefore, reads the input properties upon an update condition (e.g. a stale or otherwise invalid copy of data; Ims col. 14, line 43).

Since, as noted in the final Office Action, Ims executes the input properties of the cached object to *obtain* a fresh copy of results in the event the object is stale are invalid, Ims is executing the input properties of the cached object to *update* the cached object, rather than reading "a retrieval condition from the cache memory upon *fulfillment* of the cache update condition" as recited in, for example, claims 1 and 11 (with emphasis added).

Still, in the interest of compact prosecution only, and not for any reason of patentability, claims 1, 6, 11, and 14 have been amended to recite substantially setting "the cache update condition by acquiring data updated within a predetermined period from the database, and determining whether the number of data record is in a fixed range."

Further favorable consideration is requested.

Claim Rejections - 35 U.S.C. § 102:

Claims 1, 3-6, and 8-14 were rejected under 35 U.S.C. § 102(b) as anticipated by U.S. Patent No. 6,505,200 to Ims <u>et al.</u> (hereinafter "Ims"). The rejection is traversed to the extent and might apply to the claims as amended. Reconsideration is earnestly solicited.

In the claimed invention, as described at page 11, lines 11-25, continuing at page 12, line 1 of the specification:

The update interval setting section 34 first acquires from the database 50, data updated within a predetermined period (Step S301). The update interval setting section 34 determines whether the number of data records updated within the predetermined period is in a fixed range (Step S302). If the number of data records updated within the predetermined period is in the fixed range (Yes at Step S302), the process is terminated.

However, if the number of data records updated within the predetermined period is not in the fixed range (No at Step S302), the update interval setting section 34 sets the update interval such that the number of data records updated fall in a specific range, and then the process is terminated.

By setting the update frequency of the database 50 in this manner, the cache can be updated without increasing the load on the database.

The final clauses of claims 1 and 11, in particular, recite:

The update condition setting unit sets the cache update condition by acquiring data updated within a predetermined period from the database, and determining whether the number of data record is in a fixed range.

Ims neither teaches, discloses, nor suggests setting "the cache update condition by acquiring data updated within a predetermined period from the database, and determining whether the number of data record is in a fixed range," as recited in claims 1 and 11. In Ims, rather, a cached object is refreshed by executing the retrieval logic in the execution script of the cached object. In particular, as described column 14, lines 51-53:

For example, cached object HAO2 shown at 312 is refreshed by executing the retrieval logic in the execution script of the cached object.

Since, in Ims, cached object is refreshed by executing the retrieval logic in the execution script of the cached object, Ims is not setting "the cache update condition by acquiring data updated within a predetermined period from the database, and determining whether the number of data record is in a fixed range," as recited in claims 1 and 11.

In Ims, moreover, the retrieval logic causes a request to be sent to the back-end data

source, which returns a fresh copy of data values to be used for refreshing the cached object (i.e. re-populating the object's output properties) in the cache. In particular, as described column 14. lines 53-57:

This retrieval logic causes a request to be sent 303 to the back-end data source at host 320, which returns 304 a fresh copy of data values to be used for refreshing the cached object (i.e. re-populating the object's output properties) in the cache 300.

Since, in Ims, the retrieval logic causes a request to be sent to the back-end data source, which returns a fresh copy of data values to be used for refreshing the cached object (i.e. re-populating the object's output properties) in the cache, Ims is not setting "the cache update condition by acquiring data updated within a predetermined period from the database, and determining whether the number of data record is in a fixed range," as recited in claims 1 and 11.

In Ims, moreover, whether a cached copy is already cached or a fresh copy must be retrieved is *transparent* to the requesting application, which operates as though an actual access had been made directly to the back-end data source and a copy had been retrieved in real time. In particular, as described column 14, lines 57-62:

Whether a cached copy is already cached or a fresh copy must be retrieved is transparent to the requesting application, which operates as though an actual access (shown in FIG. 3A as imaginary access 325) had been made directly to the back-end data source and a copy had been retrieved in real time.

Since, in Ims, whether a cached copy is already cached or a fresh copy must be retrieved is transparent to the requesting application, which operates as though an actual access had been made directly to the back-end data source and a copy had been retrieved in real time, Ims is not setting "the cache update condition by acquiring data updated within a predetermined period from the database, and determining whether the number of data record is in a fixed range," as recited in claims 1 and 11.

Finally, in Ims, the refresh policy of each cached object may be periodically *evaluated* to determine whether the associated cached objects have become invalid. In particular, as described column 14, lines 62-67:

In an optional feature of this aspect, the refresh policy of each cached object may be periodically evaluated (e.g. at periodic time intervals, or in response to predetermined events) to determine whether the associated cached objects have become invalid.

Since, in Ims, the refresh policy of each cached object may be periodically evaluated to

determine whether the associated cached objects have become invalid, Ims is not setting "the cache update condition by acquiring data updated within a predetermined period from the database, and determining whether the number of data record is in a fixed range," as recited in claims 1 and 11.

The second clauses of claims 1 and 11 recite:

A cache memory that stores in a correlated form the retrieval condition and the retrieval result.

Ims neither teaches, discloses, nor suggests "a cache memory that stores in a correlated form the retrieval condition and the retrieval result," as recited in claims 1 and 11. Ims, rather, is automatically *synchronizing* one data store with another data store, even though the two stores may not share a common format. In particular, as described column 4, lines 52-56:

An object of the present invention is to provide a technique whereby one data store can be automatically synchronized with another data store, even though the two stores may not share a common format.

Since Ims is automatically synchronizing one data store with another data store, even though the two stores may not share a common format, Ims is not setting "a cache memory that stores in a correlated form the retrieval condition and the retrieval result," as recited in claims 1 and 11.

In Ims, moreover, the cached objects *component* provides for storing, and for automatically refreshing, cached objects. In particular, as described at column 9, lines 53-59:

The present invention uses a "cached objects" component (referred to equivalently herein as a "cache manager") which caches objects that are used by middleware applications to interact with back-end data sources, where the middleware application functions as a surrogate for a requesting client application. The cached objects component provides for storing, and for automatically refreshing, these objects.

Since, in Ims, the cached objects component provides for storing, and for automatically refreshing, cached objects, Ims is not setting "a cache memory that stores in a correlated form the retrieval condition and the retrieval result," as recited in claims 1 and 11.

In Ims, moreover, a cached object stored by the cached objects component has a set of *input* properties and a set of *output* properties, not a "retrieval condition" or a "retrieval result," as recited in claims 1 and 11. In particular, as described at column 10, lines 21-25:

Each object stored by the cached objects component has a set of input properties and a set of output properties (which might not be set when the object is cached) representing the information to and from the object's corresponding back-end

data source.

Since, in Ims, a cached object stored by the cached objects component has a set of input properties and a set of output properties, Ims is not setting "a cache memory that stores in a correlated form the retrieval condition and the retrieval result," as recited in claims 1 and 11.

In Ims, moreover, a cached object includes processing logic which describes how the object interacts with the *back-end* data source, and an execution method which invokes this processing logic, not a "retrieval condition" or a "retrieval result," as recited in claims 1 and 11. In particular, as described at column 10, lines 21-28:

Further, each cached object preferably includes processing logic which describes how the object interacts with the back-end data source, and an execution method which invokes this processing logic.

Since, in Ims, a cached object may include processing logic which describes how the object interacts with the back-end data source, and an execution method which invokes this processing logic, Ims is not setting "a cache memory that stores in a correlated form the retrieval condition and the retrieval result," as recited in claims 1 and 11.

Finally, in Ims, the input properties and values thereof are used as an index to *locate* objects stored in the cached objects component, not as a "retrieval condition" or a "retrieval result," as recited in claims 1 and 11. It is the stored objects *themselves*, rather, that may be categorized as either read-access (RA) or write-access (WA). In particular, as described at column 10, lines 28-32:

The input properties and values thereof are used as an index to locate objects stored in the cached objects component, where those stored objects may be categorized as either read-access (RA) or write-access (WA).

Since, in Ims, the input properties and values thereof are used as an index to locate objects stored in the cached objects component, Ims is not setting "a cache memory that stores in a correlated form the retrieval condition and the retrieval result," as recited in claims 1 and 11.

Furthermore, in Ims, a caching policy specifies when the object is to be *periodically* refreshed, such as at a particular time of day; upon occurrence of a specified event; upon an elapsed time since the last refresh, rather than according to a "retrieval condition and the retrieval result," as recited in claims 1 and 11. In particular, as described at column 13, lines 56-62:

The caching policy of an RA object preferably specifies when the object is to be periodically refreshed. For example, an object may be refreshed at a particular

time of day; upon occurrence of a specified event; upon an elapsed time since the last refresh; etc. This refresh process thereby ensures that a relatively up-todate version of the back-end data is being used when responding to client read requests.

Since, in Ims, a caching policy preferably specifies when the object is to be periodically refreshed, Ims is not setting "a cache memory that stores in a correlated form the retrieval condition and the retrieval result," as recited in claims 1 and 11.

In Ims, moreover, there is retrieval *logic* in the execution script of the cached object, not a "retrieval condition" or a "retrieval result," as recited in claims 1 and 11. In particular, as described at column 14, lines 51-62:

For example, cached object HAO2 shown at 312 is refreshed by executing the retrieval logic in the execution script of the cached object. This retrieval logic causes a request to be sent 303 to the back-end data source at host 320, which returns 304 a fresh copy of data values to be used for refreshing the cached object (i.e. re-populating the object's output properties) in the cache 300. Whether a cached copy is already cached or a fresh copy must be retrieved is transparent to the requesting application, which operates as though an actual access (shown in FIG. 3A as imaginary access 325) had been made directly to the back-end data source and a copy had been retrieved in real time.

Since, in Ims, a caching policy preferably specifies when the object is to be periodically refreshed, Ims is not setting "a cache memory that stores in a correlated form the retrieval condition and the retrieval result," as recited in claims 1 and 11.

Finally, in Ims, refresh *logic* is stored with or associated with selected replicated readaccess objects, and update *logic* is stored with or associated with selected replication writeaccess objects, not a "retrieval condition" or a "retrieval result," as recited in claims 1 and 11. In particular, as described at column 5, lines 64-67, continuing at column 6, lines 1 and 2:

Performing the replication may further comprise executing the refresh logic stored with or associated with selected replicated read-access objects for which the queued refresh requests are queued, and executing the update logic stored with or associated with selected replication write-access objects for which the queued update requests are queued.

Since, in Ims, refresh logic is stored with or associated with selected replicated read-access objects, and update logic is stored with or associated with selected replication write-access objects, Ims is not setting "a cache memory that stores in a correlated form the retrieval condition and the retrieval result," as recited in claims 1 and 11.

The fourth clauses of claims 1 and 11 recite:

An update processing unit that reads the retrieval condition from the cache memory upon fulfillment of the cache update condition.

Ims neither teaches, discloses, nor suggests "an update processing unit that reads the retrieval condition from the cache memory upon fulfillment of the cache update condition," as recited in claims 1 and 11. In Ims, rather, there is retrieval *logic* in the execution script of the cached object, not a "retrieval condition," as discussed above.

Moreover, in Ims, the object's update operation is being applied to the *back-end data* source at host 340, not the cached object. In particular, as described at column 16, lines 58-66:

When the update policy of an object having elements queued in its update queue 352 is triggered (for example, reaching a certain time of day when low-priority batched mode requests are to be processed), the updates from the queue 352 are processed by executing the update script of the corresponding object. This execution causes the object's update operation to be applied 353 to the back-end data source at host 340, by execution of the object's script using the input property values from the queued element.

Since, in Ims, the object's update operation is being applied to the back-end data source at host 340, not the cached object, Ims is not reading "the retrieval condition from the cache memory upon fulfillment of the cache update condition," as recited in claims 1 and 11. Claims 1 and 11 are submitted to be allowable. Withdrawal of the rejection of claims 1 and 11 is earnestly solicited.

Claims 3, 4, and 5 depend from claim 1 and add further distinguishing elements, while claims 12 and 13 depend from claim 11 and add further distinguishing elements. Claims 3, 4, 5, 12, and 13 are thus also submitted to be allowable. Withdrawal of the rejection of claims 3, 4, 5, 12, and 13 is also earnestly solicited.

Claims 6, 8, 9, and 10:

The final clause of claim 6 recites:

Setting the cache update condition by acquiring data updated within a predetermined period from the database, and determining whether the number of data record is in a fixed range.

Ims neither teaches, discloses, nor suggests "setting the cache update condition by acquiring data updated within a predetermined period from the database, and determining whether the number of data record is in a fixed range," as discussed above with respect to the rejections of claims 1 and 11.

The third clause of claim 6 recites:

Application Serial No. 10/766,839
Request for Continued Examination filed February 29, 2008
Reply to final Office Action mailed December 12, 2007

Reading the retrieval condition from the cache memory upon fulfillment of the cache update condition, retrieving data as the retrieval result from the database using the retrieval condition, and updating the retrieval result in the cache memory corresponding to the retrieval condition.

Ims neither teaches, discloses, nor suggests "reading the retrieval condition from the cache memory upon fulfillment of the cache update condition, retrieving data as the retrieval result from the database using the retrieval condition, and updating the retrieval result in the cache memory corresponding to the retrieval condition," as discussed above with respect to the rejections of claims 1 and 11. Claim 6 is thus also submitted to be allowable for at least those reasons discussed above respect to the rejections of claims 1 and 11. Withdrawal of the rejection of claim 6 is earnestly solicited.

Claims 8, 9, and 10 depend from claim 6 and add further distinguishing elements.

Claims 8, 9, and 10 are thus also submitted to be allowable. Withdrawal of the rejection of claims 8, 9, and 10 is earnestly solicited.

Claim 14:

The final clause of claim 14 recites:

Setting the cache update condition by acquiring data updated within a predetermined period from the database, and determining whether a number of data record updated within the predetermined period is in a fixed range.

Ims neither teaches, discloses, nor suggests "setting the cache update condition by acquiring data updated within a predetermined period from the database, and determining whether a number of data record updated within the predetermined period is in a fixed range," as discussed above with respect to the rejection of claim 1.

The second clause of claim 14 recites:

Storing a retrieval request received from a terminal that includes a retrieval condition and a retrieval result retrieved using the retrieval request in a correlated form in a cache memory.

Ims neither teaches, discloses, nor suggests " storing a retrieval request received from a terminal that includes a retrieval condition and a retrieval result retrieved using the retrieval request in a correlated form in a cache memory," as discussed above with respect to the rejection of claim 1.

The fifth clause of claim 14 recites:

Reading the retrieval condition from the cache memory upon fulfillment of the

6 2 in

Application Serial No. 10/766,839
Request for Continued Examination filed February 29, 2008
Reply to final Office Action mailed December 12, 2007

cache update condition.

Ims neither teaches, discloses, nor suggests "reading the retrieval condition from the cache memory upon fulfillment of the cache update condition," as discussed above with respect to the rejection of claim 1. Claim 14 is thus also submitted to be allowable for at least those reasons discussed above respect to the rejections of claims 1 and 11. Withdrawal of the rejection of claim 14 is earnestly solicited.

Conclusion:

Accordingly, in view of the reasons given above, it is submitted that all of claims 1, 3-6 and 8-14 are allowable over the cited references. Allowance of all claims 1, 3-6 and 8-14 and of this entire application is therefore respectfully requested.

Finally, if there are any formal matters remaining after this response, the Examiner is requested to telephone the undersigned to attend to these matters.

If there are any additional fees associated with filing of this Amendment, please charge the same to our Deposit Account No. 19-3935.

Respectfully submitted,

STAAS & HALSEY LLP
